Strings

Lecture 6

String Data Type

- A string is a sequence of characters
- A string literal uses quotes 'Hello' or "Hello"
- For strings, + means "concatenate"
- When a string contains numbers, it is still a string
- We can convert numbers in a string into a number using int()

```
>>> str1 = "Hello"
>>> str2 = 'there'
>>> bob = str1 + str2
>>> print bobHellothere
>>> str3 = '123'
>>> str3 = str3 + 1Traceback
(most recent call last): File
"<stdin>", line 1, in
<module>TypeError: cannot
concatenate 'str' and 'int' objects
>> x = int(str3) + 1
>>> print x
124
>>>
```

Reading and Converting

- We prefer to read data in using strings and then parse and convert the data as we need
- This gives us more control over error situations and/or bad user input
- Raw input numbers must be converted from strings

```
>>> name = raw_input('Enter:')
Enter:Chuck
>>> print name
Chuck
>>> apple = raw_input('Enter:')
Enter: 100
>>> x = apple - 10
Traceback (most recent call last): File "<stdin>",
line 1, in <module>TypeError: unsupported
operand type(s) for -: 'str' and 'int'
>> x = int(apple) - 10
>>> print x
90
```

Looking Inside Strings

- We can get at any single character in a string using an index specified in square brackets
- The index value must be an integer and starts at zero
- The index value can be an expression that is computed

```
a n a n a
>>> fruit = 'banana'
>>> letter = fruit[1]
>>> print letter
a
>>> n = 3
>>> w = fruit[n - 1]
>>> print w
n
```

A Character Too Far

- You will get a python error if you attempt to index beyond the end of a string.
- So be careful when constructing index values and slices

```
>>> zot = 'abc'
>>> print zot[5]
Traceback (most recent call last):
File "<stdin>", line 1, in
<module>IndexError: string index
out of range>>>
```

Strings Have Length

 There is a built-in function len that gives us the length of a string

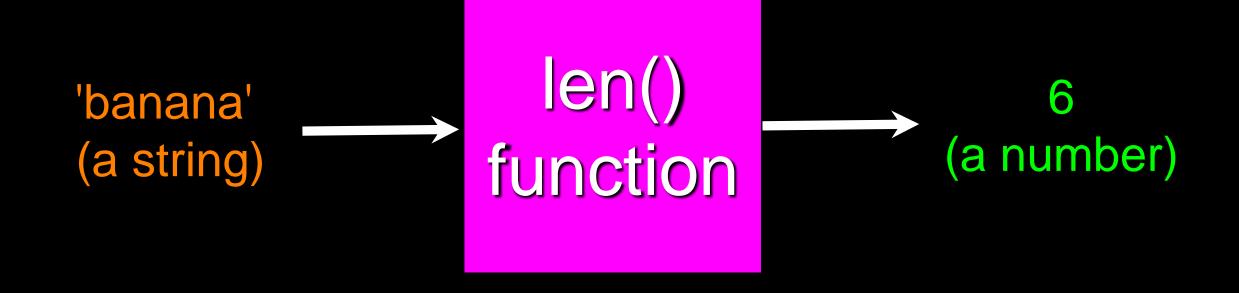

```
b a n a n a o a 0 1 2 3 4 5
```

```
>>> fruit = 'banana'
>>> print len(fruit)
6
```

Len Function

```
>>> fruit = 'banana'
>>> x = len(fruit)
>>> print x
6
```

A function is some stored code that we use. A function takes some input and produces an output.

Len Function

```
>>> fruit = 'banana'
>>> x = len(fruit)
>>> print x
6
```

A function is some stored code that we use. A function takes some input and produces an output.

'banana'
(a string)

def len(inp):
blah
blah
for x in y:
blah
blah
blah
blah

Looping Through Strings

Using a while statement and an iteration variable, and the len function, we can construct a loop to look at each of the letters in a string individually

```
fruit = 'banana' 0 b
index = 0 1 a
while index < len(fruit): 2 n
letter = fruit[index] 3 a
print index, letter
index = index + 1 5 a
```

Looping Through Strings

- A definite loop using a for statement is much more elegant
- The iteration variable is completely taken care of by the for loop

fruit = 'banana' for letter in fruit : print letter b a n a n

Looping Through Strings

- A definite loop using a for statement is much more elegant
- The iteration variable is completely taken care of by the for loop

```
fruit = 'banana'
for letter in fruit :
print letter
```

```
index = 0
while index < len(fruit):
    letter = fruit[index]
    print letter
    index = index + 1</pre>
```

b a n a n

Looping and Counting

• This is a simple loop that loops through each letter in a string and counts the number of times the loop encounters the 'a' character.

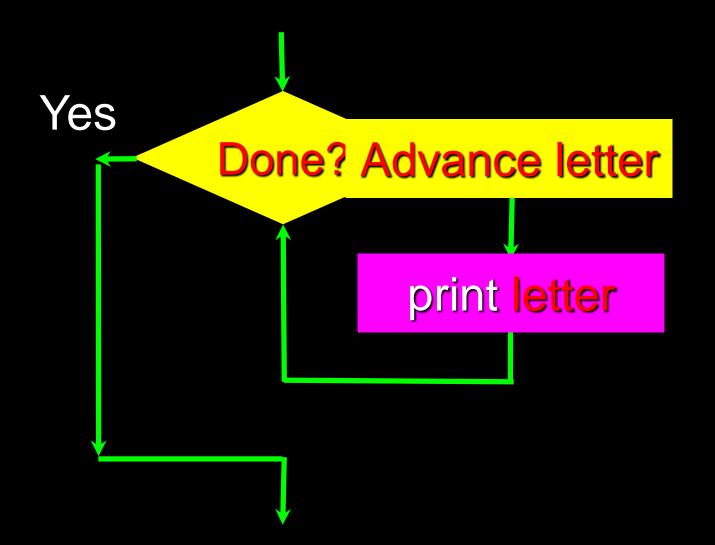

```
word = 'banana'
count = 0
for letter in word :
    if letter == 'a' :
    count = count + 1
    print count
```

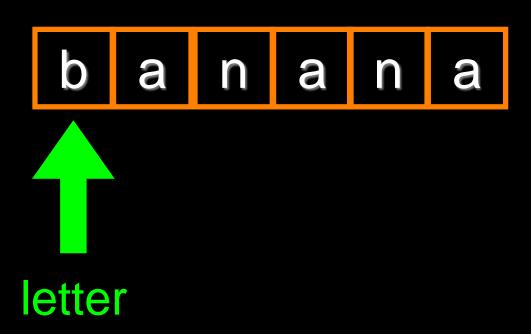

Looking deeper into in

- The iteration variable
 "iterates" though the
 sequence (ordered set)
- The block (body) of code is executed once for each value in the sequence
- The iteration variable moves through all of the values in the sequence

Six-character string

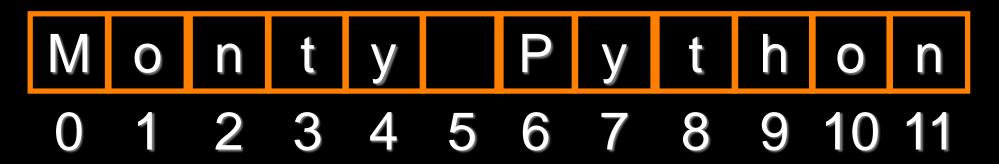

Iteration variable for letter in 'banana': print letter

for letter in 'banana':
print letter

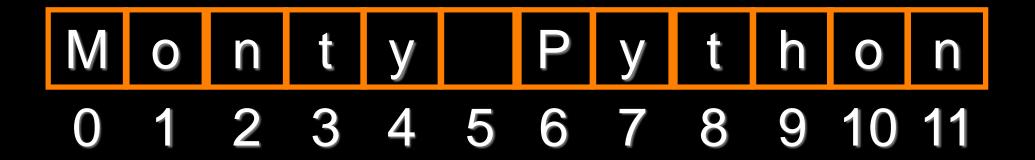

The iteration variable "iterates" though the string and the block (body) of code is executed once for each value in the sequence

- We can also look at any continuous section of a string using a colon operator
- The second number is one beyond the end of the slice
 "up to but not including"
- If the second number is beyond the end of the string, it stops at the end

```
>>> s = 'Monty Python'
>>> print s[0:4]
Mont
>>> print s[6:7]
P
>>> print s[6:20]
Python
```

Slicing Strings

• If we leave off the first number or the last number of the slice, it is assumed to be the beginning or end of the string respectively

```
>>> s = 'Monty Python'
>>> print s[:2]
Mo
>>> print s[8:]
thon>>> print s[:]
Monty Python
```

Slicing Strings

String Concatenation

 When the + operator is applied to strings, it means "concatenation"

```
>>> a = 'Hello'
>>> b = a + 'There'
>>> print b
HelloThere
>>> C = a + ' ' + 'There'
>>> print c
Hello There
>>>
```

Using in as an Operator

- The in keyword can also be used to check to see if one string is "in" another string
- The in expression is a logical expression and returns True or False and can be used in an if statement

String Comparison

```
if word == 'banana':
     print 'All right, bananas.'
if word < 'banana':
     print 'Your word,' + word + ', comes before banana.'
elif word > 'banana':
     print 'Your word,' + word + ', comes after banana.'
else:
     print 'All right, bananas.'
```

String Library

- Python has a number of string functions which are in the string library
- These functions are already built into every string - we invoke them by appending the function to the string variable
- These functions do not modify the original string, instead they return a new string that has been altered

```
>>> greet = 'Hello Bob'
>>> zap = greet.lower()
>>> print zap
hello bob
>>> print greet
Hello Bob
>>> print 'Hi There'.lower()
hi there
>>>
```

```
>>> stuff = 'Hello world'
>>> type(stuff)
<type 'str'
>>>> dir(stuff)
['capitalize', 'center', 'count', 'decode', 'encode',
'endswith', 'expandtabs', 'find', 'format',
'index', 'isalnum', 'isalpha', 'isdigit', 'islower', '
isspace', 'istitle', 'isupper', 'join', 'ljust', 'lower',
 'Istrip', 'partition', 'replace', 'rfind', 'rindex', 'rjust',
 'rpartition', 'rsplit', 'rstrip', 'split', 'splitlines', 'startswith',
 'strip', 'swapcase', 'title', 'translate', 'upper', 'zfill']
```

str. replace(old, new[, count])

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

str. rfind(sub[, start[, end]])

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within s[start,end]. Optional arguments *start* and *end* are interpreted as in slice notation. Return on failure.

str.rindex(sub[, start[, end]])

Like rfind() but raises valueError when the substring sub is not found.

str. rjust (width[, fillchar])

Return the string right justified in a string of length width. Padding is done using the specified fillchar (default is a space). The original string is returned if width is less than len(s).

http://docs.python.org/lib/string-methods.html

String Library

```
str.capitalize()str.replace(old, new[, count])str.center(width[, fillchar])str.lower()str.endswith(suffix[, start[, end]])str.rstrip([chars])str.find(sub[, start[, end]])str.strip([chars])str.lstrip([chars])str.upper()
```

http://docs.python.org/lib/string-methods.html

Searching a String

- We use the find() function to search for a substring within another string
- find() finds the first occurance of the substring
- If the substring is not found, find() returns -1
- Remember that string position starts at zero

```
b a n a n a
0 1 2 3 4 5
```

```
>>> fruit = 'banana'
>>> pos = fruit.find('na')
>>> print pos
2
>>> aa = fruit.find('z')
>>> print aa
-1
```

Making everything UPPER CASE

- You can make a copy of a string in lower case or upper case
- Often when we are searching for a string using find() - we first convert the string to lower case so we can search a string regardless of case

```
>>> greet = 'Hello Bob'
>>> nnn = greet.upper()
>>> print nnn
HELLO BOB
>>> www = greet.lower()
>>> print www
hello bob
>>>
```

Search and Replace

- The replace()
 function is like a
 "search and
 replace" operation
 in a word processor
- It replaces all occurrences of the search string with the replacement string

```
>>> greet = 'Hello Bob'
>>> nstr = greet.replace('Bob','Jane')
>>> print nstr
Hello Jane
>>> greet = 'Hello Bob'
>>> nstr = greet.replace('o','X')
>>> print nstrHellX BXb
>>>
```

Stripping Whitespace

- Sometimes we want to take a string and remove whitespace at the beginning and/or end
- Istrip() and rstrip() to the left and right only
- strip() Removes both begin and ending whitespace

```
>>> greet = ' Hello Bob
>>> greet.lstrip()
'Hello Bob '
>>> greet.rstrip()
' Hello Bob'
>>> greet.strip()
'Hello Bob'
>>>
```

Prefixes

- >>> line = 'Please have a nice day'
- >>> line.startswith('Please')True
- >>> line.startswith('p')False

Summary

- String type
- Read/Convert
- Indexing strings []
- Slicing strings [2:4]
- Looping through strings with for and while
- Concatenating strings with +
- in as an operator
- String comparison
- String library
- Searching in strings
- Replacing text
